ExtREME COMPUTING

ParMA: a major advance in High-Performance Computing (HPC) in Europe

Information Technology for European Advancement (ITEA) is a collaborative program founded by European high-tech enterprises, including Bull, under the auspices of the EUREKA initiative, with the aim of stimulating and supporting innovative research and development projects in information technology.

Since it was established twelve years ago, ITEA and its successor ITEA 2 have co-financed more than a hundred projects, involving over 1,000 partners, enterprises and research laboratories in 30 countries. Every year, ITEA singles out those projects that have achieved the most outstanding results, from among the 20 or so currently in progress. In 2010 the ParMA project, led by Bull, has received the highest distinction, the Gold Achievement Award, with the committee commenting that they were: “impressed by the innovative character and rapid results achieved by ParMA”.

Tangible and spectacular results

Launched in June 2007 and partly founded by the French Ministry for the Economy, Industry & Employment, ParMA (Parallel Programming for Multi-Cores Architectures) has enabled the development of an Open Source, multi-platform tool for optimizing parallel computer simulation applications. The tool, named UNITE, has contributed to the enhancement of bullx®, voted the world’s best supercomputer in 2009 by HPCwire magazine. These important innovations in parallel computing have immediately led to some tangible and spectacular results. Most notably, one of the German partners, RECOM Services, won a contract for their 3D-combustion simulation tool, used to optimize fossil-fueled power stations, which enables their customer to save €125,000 and some 16,000 tons of CO₂ emissions annually, thanks to the increase of performance obtained using the ParMA tools. At a time when High-Performance Computing (HPC) is becoming an indisputable, strategic driver for innovation and competitiveness, the ParMA project has made a striking contribution to European industry by providing it with such high caliber hardware and software solutions.

The aim of the ParMA project was to develop technologies that could fully exploit the multi-core architectures on which supercomputers are now based. Indeed, the advent of multi-core processors has enabled spectacular advances in computing power. Nonetheless, exploiting the true potential involves splitting up operations and distributing them between the various cores, something that requires the parallelization of applications. It’s not enough simply to re-write the code: the loading between the processing nodes must be rebalanced, and exchanges of data also have to be limited, as these then become the new limiting factor for performance. To this end you can tweak the various aspects of the logic (optimizing algorithms, using intelligent data management, setting up
specialist software development tools and suppliers of multi-core systems, as well as research laboratories and university computing centers including those at Jülich, Stuttgart and Dresden. As project leader, Bull has supplied the development and testing platform, a bullx HPC cluster located at les Clayes-sous-Bois (close to Paris), and has contributed its expertise in infrastructure tuning, especially since the relationship between software and hardware has to be extremely close when it comes to achieving maximum performance.

In addition to the development of UNITE1 – the most advanced software package as far finalization and optimization of parallel applications is concerned – and improvements made to bullx, ParMA projects have resulted in the optimization of more than a dozen applications – with similar results to those obtained by RECOM Services – involving simulations ranging from casting modeling to numerical dosimetry used to simulate and evaluate dose exposure in real-time, thus characterizing the risk when people are exposed in a radioactive environment. For example, at the last count the processing sequence of a metal forming simulation tool has been reduced from 13 hours to just 1 hour 30 minutes. Thanks to the excellent spirit of cooperation at the heart of this project, all participants have been able to significantly improve their knowledge and mastery of multi-core HPC systems, especially in the research laboratories. The latter have had the opportunity to take part in real programs and work with real data from real businesses, and so have had access to first-rate experimental material of immense value to them. It is these outcomes and the mutual enrichment of both the industry and research sectors in Europe that exemplifies all that ITEA has set out to promote, and that has brought ParMA its well deserved reward.

Moving towards Exascale computing
Today, the ParMA project is being extended in the form of a new project known as H4H (Hybrid for HPC), which brings together the existing community, along with some new, major industrial and scientific partners. The aim of this project is to take full advantage of the hybrid CPU+GPU architectures that are opening up new horizons for High-Performance Computing. Because ParMA – and now H4H – are facilitating much greater understanding of and expertise in the factors affecting supercomputer performance, they represent essential steps towards Exascale computing in Europe.

(1) UNITE (UNified Integrated Tool Environment), can run on most HPC environments, and can be downloaded from http://apps.fz-juelich.de/unite/
Bull is ranked among the “Top 5 Vendors to Watch in 2011” in HPCwire Readers’ Choice Awards

HPCwire Reader’s Choice Award confirms Bull as a world-class leader in the HPC market

Bull has been recognized in the annual HPCwire Readers’ Choice Awards, presented at the 2010 International Conference for High Performance Computing, Networking, Storage and Analysis (SC10), in New Orleans, Louisiana. The list of winners was revealed at the HPCwire booth at the event.

Back in November 2009, at SC09, bullx was named as the world’s best HPC server product or technology and ranked among the top five new products to watch. This year is the turn for Bull to be recognized with the following honor: Readers’ Choice - Top 5 Vendors to Watch in 2011.

Bull is one of the very few companies in the world designing and delivering from teraflops- to petaflops-class supercomputers for running 24h/24 applications. The HPCwire readers’ choice confirms Bull as a global player and a world-class leader in the Extreme Computing domain.

The coveted HPCwire Readers’ Choice Awards are determined through online polling of the global HPCwire audience, along with a rigorous selection process involving HPCwire editors and industry luminaries. The awards are an annual feature of the publication and constitute prestigious recognition from the HPC community. These awards are revealed each year to kick off the SC conference, which showcases high performance computing, networking, storage, and data analysis.

“HPCwire readers are among the most informed in the HPC community and these awards represent which HPC-related companies are making the biggest impacts in mind-share within this community,” said Tom Tabor, publisher of HPCwire. “The HPCwire Readers’ and Editors’ Choice Awards send a strong message to the recipients that those in the global HPC community recognize their work, and consider their efforts meritorious. Our congratulations go out to all the winners.”
